Chapter 14: Transactions

Chapter 14: Transactions

- Transaction Concept

- Transaction State

- Concurrent Executions

- Serializability

- Recoverability

- Implementation of Isolation

- Transaction Definition in SQL

- Testing for Serializability.

Transaction Concept

- A **transaction** is a *unit* of program execution that accesses and possibly updates various data items.

- E.g. transaction to transfer $50 from account A to account B:
    1. **read**(*A*)
    2. *A* := *A* − 50
    3. **write**(*A*)
    4. **read**(*B*)
    5. *B* := *B* + 50
    6. **write**(*B*)

- Two main issues to deal with:
    - Failures of various kinds, such as hardware failures and system crashes
    - Concurrent execution of multiple transactions

Example of Fund Transfer

- Transaction to transfer $50 from account A to account B:

    1. **read**(A)
    2. $A := A - 50$
    3. **write**(A)
    4. **read**(B)
    5. $B := B + 50$
    6. **write**($B)$

- **Atomicity requirement**

    - if the transaction fails after step 3 and before step 6, money will be "lost" leading to an inconsistent database state

        ▸ Failure could be due to software or hardware

    - the system should ensure that updates of a partially executed transaction are not reflected in the database

- **Durability requirement** — once the user has been notified that the transaction has completed (i.e., the transfer of the $50 has taken place), the updates to the database by the transaction must persist even if there are software or hardware failures.

Example of Fund Transfer (Cont.)

- Transaction to transfer $50 from account A to account B:
    1. **read**(*A*)
    2. *A* := *A* − 50
    3. **write**(*A*)
    4. **read**(*B*)
    5. *B* := *B* + 50
    6. **write**(*B)*
- **Consistency requirement** in above example:
    - the sum of A and B is unchanged by the execution of the transaction
- In general, consistency requirements include
    - ▶ Explicitly specified integrity constraints such as primary keys and foreign keys
    - ▶ Implicit integrity constraints
        - – e.g. sum of balances of all accounts, minus sum of loan amounts must equal value of cash-in-hand
    - A transaction must see a consistent database.
    - During transaction execution the database may be temporarily inconsistent.
    - When the transaction completes successfully the database must be consistent
        - ▶ Erroneous transaction logic can lead to inconsistency

Example of Fund Transfer (Cont.)

- **Isolation requirement** — if between steps 3 and 6, another transaction T2 is allowed to access the partially updated database, it will see an inconsistent database (the sum $A + B$ will be less than it should be).

T1	T2
1. **read**(A)	
2. $A := A - 50$	
3. **write**(A)	
	read(A), read(B), print(A+B)
4. **read**(B)	
5. $B := B + 50$	
6. **write**(B	

- Isolation can be ensured trivially by running transactions **serially**
  - that is, one after the other.
- However, executing multiple transactions concurrently has significant benefits, as we will see later.

ACID Properties

A **transaction** is a unit of program execution that accesses and possibly updates various data items.To preserve the integrity of data the database system must ensure:

- **Atomicity.** Either all operations of the transaction are properly reflected in the database or none are.

- **Consistency.** Execution of a transaction in isolation preserves the consistency of the database.

- **Isolation.** Although multiple transactions may execute concurrently, each transaction must be unaware of other concurrently executing transactions. Intermediate transaction results must be hidden from other concurrently executed transactions.

    - That is, for every pair of transactions T_i and T_j, it appears to T_i that either T_j finished execution before T_i started, or T_j started execution after T_i finished.

- **Durability.** After a transaction completes successfully, the changes it has made to the database persist, even if there are system failures.
Transaction State

- **Active** – the initial state; the transaction stays in this state while it is executing

- **Partially committed** – after the final statement has been executed.

- **Failed** -- after the discovery that normal execution can no longer proceed.

- **Aborted** – after the transaction has been rolled back and the database restored to its state prior to the start of the transaction. Two options after it has been aborted:

  - restart the transaction
    - can be done only if no internal logical error
  - kill the transaction

- **Committed** – after successful completion.

Transaction State (Cont.)

Concurrent Executions

- Multiple transactions are allowed to run concurrently in the system. Advantages are:

  - **increased processor and disk utilization**, leading to better transaction *throughput*

    - E.g. one transaction can be using the CPU while another is reading from or writing to the disk

  - **reduced average response time** for transactions: short transactions need not wait behind long ones.

- **Concurrency control schemes** – mechanisms to achieve isolation

  - that is, to control the interaction among the concurrent transactions in order to prevent them from destroying the consistency of the database

    - Will study in Chapter 16, after studying notion of correctness of concurrent executions.

Schedules

- **Schedule** – a sequences of instructions that specify the chronological order in which instructions of concurrent transactions are executed

  - a schedule for a set of transactions must consist of all instructions of those transactions

  - must preserve the order in which the instructions appear in each individual transaction.

- A transaction that successfully completes its execution will have a commit instructions as the last statement

  - by default transaction assumed to execute commit instruction as its last step

- A transaction that fails to successfully complete its execution will have an abort instruction as the last statement

Schedule 1

- Let T_1 transfer \$50 from *A* to *B*, and T_2 transfer 10% of the balance from *A* to *B*.

- A serial schedule in which T_1 is followed by T_2 :

T_1	T_2
read (A)	
A := A − 50	
write (A)	
read (B)	
B := B + 50	
write (B)	
commit	
	read (A)
	temp := A * 0.1
	A := A - temp
	write (A)
	read (B)
	B := B + temp
	write (B)
	commit

Schedule 2

- A serial schedule where T_2 is followed by T_1

T_1	T_2
	read (A)
	temp := A * 0.1
	A := A - temp
	write (A)
	read (B)
	B := B + temp
	write (B)
	commit
read (A)	
A := A − 50	
write (A)	
read (B)	
B := B + 50	
write (B)	
commit	

Schedule 3

- Let T_1 and T_2 be the transactions defined previously. The following schedule is not a serial schedule, but it is *equivalent* to Schedule 1.

T_1	T_2
read (A)	
A := A − 50	
write (A)	
	read (A)
	temp := A * 0.1
	A := A - temp
	write (A)
read (B)	
B := B + 50	
write (B)	
commit	
	read (B)
	B := B + temp
	write (B)
	commit

In Schedules 1, 2 and 3, the sum A + B is preserved.

Schedule 4

- The following concurrent schedule does not preserve the value of $(A + B)$.

T_1	T_2
read (A) $A := A - 50$	
	read (A) $temp := A * 0.1$ $A := A - temp$ write (A) read (B)
write (A) read (B) $B := B + 50$ write (B) commit	
	$B := B + temp$ write (B) commit

Serializability

- **Basic Assumption** – Each transaction preserves database consistency.

- Thus serial execution of a set of transactions preserves database consistency.

- A (possibly concurrent) schedule is serializable if it is equivalent to a serial schedule. Different forms of schedule equivalence give rise to the notions of:

    1. **conflict serializability**
    2. **view serializability**

Simplified view of transactions

- We ignore operations other than **read** and **write** instructions

- We assume that transactions may perform arbitrary computations on data in local buffers in between reads and writes.

- Our simplified schedules consist of only **read** and **write** instructions.

Conflicting Instructions

■ Instructions I_i and I_j of transactions T_i and T_j respectively, **conflict** if and only if there exists some item Q accessed by both I_i and I_j, and at least one of these instructions wrote Q.

1. $I_i = $ **read**(Q), $I_j = $ **read**(Q). I_i and I_j don't conflict.
2. $I_i = $ **read**(Q), $I_j = $ **write**(Q). They conflict.
3. $I_i = $ **write**(Q), $I_j = $ **read**(Q).   They conflict
4. $I_i = $ **write**(Q), $I_j = $ **write**(Q). They conflict

■ Intuitively, a conflict between I_i and I_j forces a (logical) temporal order between them.

● If I_i and I_j are consecutive in a schedule and they do not conflict, their results would remain the same even if they had been interchanged in the schedule.

Conflict Serializability

- If a schedule S can be transformed into a schedule $S´$ by a series of swaps of non-conflicting instructions, we say that S and $S´$ are **conflict equivalent**.

- We say that a schedule S is **conflict serializable** if it is conflict equivalent to a serial schedule

Conflict Serializability (Cont.)

- Schedule 3 can be transformed into Schedule 6, a serial schedule where T_2 follows T_1, by series of swaps of non-conflicting instructions. Therefore Schedule 3 is conflict serializable.

T_1	T_2
read (A)	
write (A)	
	read (A)
	write (A)
read (B)	
write (B)	
	read (B)
	write (B)

Schedule 3

T_1	T_2
read (A)	
write (A)	
read (B)	
write (B)	
	read (A)
	write (A)
	read (B)
	write (B)

Schedule 6

Conflict Serializability (Cont.)

- Example of a schedule that is not conflict serializable:

T_3	T_4
read (Q)	
	write (Q)
write (Q)	

- We are unable to swap instructions in the above schedule to obtain either the serial schedule $< T_3, T_4 >$, or the serial schedule $< T_4, T_3 >$.

View Serializability

- Let S and S' be two schedules with the same set of transactions. S and S' are **view equivalent** if the following three conditions are met, for each data item Q,

    1. If in schedule S, transaction T_i reads the initial value of Q, then in schedule S' also transaction T_i must read the initial value of Q.

    2. If in schedule S transaction T_i executes **read**(Q), and that value was produced by transaction T_j (if any), then in schedule S' also transaction T_i must read the value of Q that was produced by the same **write**(Q) operation of transaction T_j.

    3. The transaction (if any) that performs the final **write**(Q) operation in schedule S must also perform the final **write**(Q) operation in schedule S'.

  As can be seen, view equivalence is also based purely on **reads** and **writes** alone.

View Serializability (Cont.)

- A schedule *S* is **view serializable** if it is view equivalent to a serial schedule.

- Every conflict serializable schedule is also view serializable.

- Below is a schedule which is view-serializable but *not* conflict serializable.

T_{27}	T_{28}	T_{29}
read (Q)		
	write (Q)	
write (Q)		
		write (Q)

- What serial schedule is above equivalent to?

- Every view serializable schedule that is not conflict serializable has **blind writes**.

Other Notions of Serializability

- The schedule below produces same outcome as the serial schedule $< T_1, T_5 >$, yet is not conflict equivalent or view equivalent to it.

T_1	T_5
read (A)	
$A := A - 50$	
write (A)	
	read (B)
	$B := B - 10$
	write (B)
read (B)	
$B := B + 50$	
write (B)	
	read (A)
	$A := A + 10$
	write (A)

- Determining such equivalence requires analysis of operations other than read and write.

Testing for Serializability

- Consider some schedule of a set of transactions T_1, T_2, ..., T_n

- **Precedence graph** — a direct graph where the vertices are the transactions (names).

- We draw an arc from T_i to T_j if the two transaction conflict, and T_i accessed the data item on which the conflict arose earlier.

- We may label the arc by the item that was accessed.

- **Example 1**
Test for Conflict Serializability

- A schedule is conflict serializable if and only if its precedence graph is acyclic.

- Cycle-detection algorithms exist which take order n^2 time, where n is the number of vertices in the graph.

  - (Better algorithms take order $n + e$ where e is the number of edges.)

- If precedence graph is acyclic, the serializability order can be obtained by a *topological sorting* of the graph.

  - This is a linear order consistent with the partial order of the graph.

  - For example, a serializability order for Schedule A would be
    $T_5 \rightarrow T_1 \rightarrow T_3 \rightarrow T_2 \rightarrow T_4$

    ‣ Are there others?

(a)

(b)

(c)
Test for View Serializability

- The precedence graph test for conflict serializability cannot be used directly to test for view serializability.

    - Extension to test for view serializability has cost exponential in the size of the precedence graph.

- The problem of checking if a schedule is view serializable falls in the class of *NP*-complete problems.

    - Thus existence of an efficient algorithm is *extremely* unlikely.

- However practical algorithms that just check some **sufficient conditions** for view serializability can still be used.

Recoverable Schedules

Need to address the effect of transaction failures on concurrently running transactions.

- **Recoverable schedule** — if a transaction T_j reads a data item previously written by a transaction T_i, then the commit operation of T_i appears before the commit operation of T_j.

- The following schedule (Schedule 11) is not recoverable if T_9 commits immediately after the read

T_8	T_9
read (A)	
write (A)	
	read (A)
	commit
read (B)	

- If T_8 should abort, T_9 would have read (and possibly shown to the user) an inconsistent database state. Hence, database must ensure that schedules are recoverable.

Cascading Rollbacks

- **Cascading rollback** – a single transaction failure leads to a series of transaction rollbacks. Consider the following schedule where none of the transactions has yet committed (so the schedule is recoverable)

T_{10}	T_{11}	T_{12}
read (A)		
read (B)		
write (A)		
	read (A)	
	write (A)	
		read (A)
abort		

If T_{10} fails, T_{11} and T_{12} must also be rolled back.

- Can lead to the undoing of a significant amount of work

Cascadeless Schedules

- **Cascadeless schedules** — cascading rollbacks cannot occur; for each pair of transactions T_i and T_j such that T_j reads a data item previously written by T_i, the commit operation of T_i appears before the read operation of T_j.

- Every cascadeless schedule is also recoverable

- It is desirable to restrict the schedules to those that are cascadeless

Concurrency Control

- A database must provide a mechanism that will ensure that all possible schedules are

    - either conflict or view serializable, and

    - are recoverable and preferably cascadeless

- A policy in which only one transaction can execute at a time generates serial schedules, but provides a poor degree of concurrency

    - Are serial schedules recoverable/cascadeless?

- Testing a schedule for serializability *after* it has executed is a little too late!

- **Goal** – to develop concurrency control protocols that will assure serializability.

Concurrency Control (Cont.)

- Schedules must be conflict or view serializable, and recoverable, for the sake of database consistency, and preferably cascadeless.

- A policy in which only one transaction can execute at a time generates serial schedules, but provides a poor degree of concurrency.

- Concurrency-control schemes tradeoff between the amount of concurrency they allow and the amount of overhead that they incur.

- Some schemes allow only conflict-serializable schedules to be generated, while others allow view-serializable schedules that are not conflict-serializable.

Concurrency Control vs. Serializability Tests

- Concurrency-control protocols allow concurrent schedules, but ensure that the schedules are conflict/view serializable, and are recoverable and cascadeless .

- Concurrency control protocols generally do not examine the precedence graph as it is being created
  - Instead a protocol imposes a discipline that avoids nonseralizable schedules.
  - We study such protocols in Chapter 16.

- Different concurrency control protocols provide different tradeoffs between the amount of concurrency they allow and the amount of overhead that they incur.

- Tests for serializability help us understand why a concurrency control protocol is correct.

Weak Levels of Consistency

- Some applications are willing to live with weak levels of consistency, allowing schedules that are not serializable

    - E.g. a read-only transaction that wants to get an approximate total balance of all accounts

    - E.g. database statistics computed for query optimization can be approximate (why?)

    - Such transactions need not be serializable with respect to other transactions

- Tradeoff accuracy for performance

Levels of Consistency in SQL-92

- **Serializable** — default

- **Repeatable read** — only committed records to be read, repeated reads of same record must return same value. However, a transaction may not be serializable – it may find some records inserted by a transaction but not find others.

- **Read committed** — only committed records can be read, but successive reads of record may return different (but committed) values.

- **Read uncommitted** — even uncommitted records may be read.

- Lower degrees of consistency useful for gathering approximate information about the database

- Warning: some database systems do not ensure serializable schedules by default
    - E.g. Oracle and PostgreSQL by default support a level of consistency called snapshot isolation (not part of the SQL standard)

Transaction Definition in SQL

- Data manipulation language must include a construct for specifying the set of actions that comprise a transaction.

- In SQL, a transaction begins implicitly.

- A transaction in SQL ends by:

  - **Commit work** commits current transaction and begins a new one.

  - **Rollback work** causes current transaction to abort.

- In almost all database systems, by default, every SQL statement also commits implicitly if it executes successfully

  - Implicit commit can be turned off by a database directive

    - E.g. in JDBC,   connection.setAutoCommit(false);
